## Why do we need deep critical learning?

To learn meaningful patterns under real-world adverse cases.

Horse class: The first three images are deer semantically.

This video is labelled as the person wearing black skirt.

This video is labelled as the person wearing green shirt.

**Figure:** Display of abnormal training examples highlighted by red boxes.

# Adverse cases in real-world data

Out-of-distribution anomalies: Know the unknown

- Some inputs contain only background and no semantic information at all.
- Some may contain a object that does not belong to any class in the training set.

# Adverse cases in real-world data

In-distribution anomalies: Detect => Ignore or Correct

- Label noise arising from:
  - ① Noisy annotations: e.g., some images of deer may be wrongly annotated to horse.
  - ② Missing annotations: we may use some algorithms to predict their labels. If so, the predicted labels are not 100% accurate.
- When an input contains more than one object, it becomes ambiguous without any prior.

# Objectives of critical/robust deep learning

## What is the meaning of critical learning here?

---

- **To learn meaningful patterns** on semantically clean training data (where noise may exist, however, the semantic matching from observations to annotations is highly correct).
- **Without fitting wrong patterns** on semantically wrong training data, so that the learning process of a model is not contaminated.
- **Generalisation to unseen data.**

# Robustness against adverse cases

What should a learning process ideally look like?

- $p_i = p(y_i|x_i)$  : predicted relevance between an observation  $x_i$  and its label  $y_i$ .
- We train ResNet-56 on CIFAR-10 with 40% symmetric label noise.

## Generalise to unseen data

# Robust learning via example weighting

Example weighting is universal in deep learning

We define our interpretation of example weighting [11]:

**Definition** (Example Weighting). *In gradient-based optimization, the loss's derivative of an example can be interpreted as its effect on the update of a model [4, 1]. Therefore, a derivative's magnitude function can be treated as a weighting scheme from the viewpoint of example weighting.*

Accordingly, one technique that leads to a change of the derivative magnitude function, is equivalent to, modifying an example weighting scheme.

# Derivative manipulation (DM)

## Fundamental research questions and conclusions

- 1 What kind of examples to focus on during training? How to weight them properly?
- 2 A loss function is okay to be non-symmetric, unbounded, or even non-differentiable.
- 3 Is a loss function necessary for deriving the gradient used for back-propagation?
- 4 When a training set contains a higher label noise rate, we should focus on easier training examples for better generalisation!

## Standard practice versus DM

**Figure:** Black and red arrows denote forward process and gradient back-propagation, respectively.

# Example weighting via EDFs

## Summary and definitions

**Definition 1** (Emphasis Mode  $\psi$ ). We define the emphasis mode to be  $p_i$  of examples whose weights are the largest, i.e.,  
$$\psi = \arg \max_{p_i} w_i, \quad \psi \in [0, 1].$$

For example, by ‘emphasis mode is 0 in CCE’ we mean those images with  $p_i = 0$  own the highest weights.

**Definition 2** (Emphasis Variance  $\sigma$ ).  $\sigma = E((w_i - E(w_i))^2)$ , where  $E(\cdot)$  denotes the expectation of a variable.

**Figure:** We observe noisy examples have much less  $p_i$  than clean ones, thus being more difficult examples.

## Core research questions [12]

- ① In Self LC, how much should we trust a learner to leverage its knowledge?
  - The trust score is fixed or updated stage-by-stage in prior work.
  - ProSelfLC modifies the target **progressively, is end-to-end trainable, and requires negligible extra cost.**
- ② Should we penalise a low-entropy status or reward it?
  - OR methods penalise low entropy while LC rewards it.
  - ProSelfLC [12] redirects and promotes entropy minimisation.
- ③ Towards a low-temperature entropy state:
  - Using the standard training setting, a trained network is of low confidence when severe noise exists, making it hard to leverage its high-entropy self knowledge.
  - Therefore, we decrease the entropy of self knowledge using a low temperature before exploiting it to correct labels.

# BEYOND SEMANTIC CLASS

## THE SIMILARITY STRUCTURE IN A LABEL DISTRIBUTION

A label distribution defines what to learn:

- **Definition 1** (*Semantic Class*). Given a target label distribution  $\tilde{q}(x) \in \mathbb{R}^C$ , the semantic class is defined by  $\arg \max_j \tilde{q}(j|x)$ , i.e., the class whose probability is the largest.
- **Definition 2** (*Similarity Structure*). In CCE, LS and CP, a data point has an identical probability of belonging to other classes except for the semantic class. Instead, in LC, a target label distribution captures the probability difference of an example being predicted to every class. We define it to be the similarity structure of one example versus all training classes.

# An overview of label (target) modification

OR(LS and CP) + LC(Self LC and Non-self LC)

$\tilde{\mathbf{q}}_{\text{LS}} = (1 - \epsilon)\mathbf{q} + \epsilon\mathbf{u}$	$\tilde{\mathbf{q}}_{\text{CP}} = (1 - \epsilon)\mathbf{q} - \epsilon\mathbf{p}$
<div style="border: 1px dashed black; padding: 10px;"><math display="block">\begin{matrix} \mathbf{q} &amp; \mathbf{u} \\ \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} &amp; + \begin{pmatrix} 1/3 \\ 1/3 \\ 1/3 \end{pmatrix} \Rightarrow \begin{pmatrix} (1 - \epsilon) + \epsilon/3 \\ \epsilon/3 \\ \epsilon/3 \end{pmatrix} \\ 1 - \epsilon &amp; \epsilon \end{matrix}</math></div> <p style="text-align: center;">LS</p>	<div style="border: 1px dashed black; padding: 10px;"><math display="block">\begin{matrix} \mathbf{q} &amp; \mathbf{p} \\ \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} &amp; - \begin{pmatrix} 1/2 \\ 1/3 \\ 1/6 \end{pmatrix} \Rightarrow \begin{pmatrix} (1 - \epsilon) - \epsilon/2 \\ -\epsilon/3 \\ -\epsilon/6 \end{pmatrix} \Leftrightarrow \begin{pmatrix} (1 - \epsilon) - \epsilon/2 \\ 0 \\ 0 \end{pmatrix} \\ 1 - \epsilon &amp; \epsilon \end{matrix}</math></div> <p style="text-align: center;">CP</p>

OR includes LS [9] and CP [7], which smoothes similarity structure:

- LS softens a target by adding a uniform label distribution.
- CP changes the probability 1 to a smaller value  $1 - \epsilon$  in the one-hot target.

The double-ended arrow means factual equivalence, because an output is definitely non-negative after a softmax layer.

# An overview of label (target) modification

OR(LS and CP) + LC(Self LC and Non-self LC)

$$\bar{q}_{LC} = (1 - \epsilon)q + \epsilon p$$

target learner   $p$

$q$	$p$
$\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$	$\begin{pmatrix} 1/2 \\ 1/3 \\ 1/6 \end{pmatrix}$
$1 - \epsilon$	$\epsilon$

 $\Rightarrow \begin{pmatrix} (1 - \epsilon) + \epsilon/2 \\ \epsilon/3 \\ \epsilon/6 \end{pmatrix}$

Self LC:  $p$  is the output of a learner itself.

$q$	$p$
$\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$	$\begin{pmatrix} 1/2 \\ 1/6 \\ 1/3 \end{pmatrix}$
$1 - \epsilon$	$\epsilon$

 $\Rightarrow \begin{pmatrix} (1 - \epsilon) + \epsilon/2 \\ \epsilon/6 \\ \epsilon/3 \end{pmatrix}$ 

auxiliary learner   $p$  target learner 

Non-self LC:  $p$  is the output of an auxiliary learner.

- LC contains Self LC [6, 8, 10] and Non-self LC [5].
- The convex combination parameter  $\epsilon$  defines how much a predicted label distribution is trusted.

## Why do we choose to improve Self LC?

- ① OR methods naively penalise confident outputs **without leveraging easily accessible knowledge** from other learners or itself.
- ② Non-self LC relies on accurate **auxiliary models**.
- ③ Self LC:
  - It exploits its own knowledge;
  - It requires no extra learners;
  - However, **how much should we trust a learner to leverage its knowledge?**

# Overview of existing variants of Self LC

Without considering a model's knowledge grows as time goes

- ① In bootstrapping,  $\epsilon$  is fixed throughout the training process.
- ② Joint Optimisation fully trusts a learner by setting  $\epsilon = 1$ , and uses stage-wise training to gradually train the model.
  - Stage-wise training requires a significant human intervention and is time-consuming in practice.
- ③ Requirements of improving Self LC
  - End-to-end trainable.
  - Negligible extra cost.
  - Modifies the target progressively and adaptively as training goes.

# ProSelfLC

## Self Trust according to Training Time and Confidence

$\epsilon$  indicates how much a predicted label distribution is trusted.  
For any  $x$ , we summarise the loss and modified label:

$$\begin{aligned}L(\tilde{q}_{\text{ProSelfLC}}, \mathbf{p}; \epsilon_{\text{ProSelfLC}}) &= H(\tilde{q}_{\text{ProSelfLC}}, \mathbf{p}) = E_{\tilde{q}_{\text{ProSelfLC}}}(-\log \mathbf{p}), \\ \tilde{q}_{\text{ProSelfLC}} &= (1 - \epsilon_{\text{ProSelfLC}})\mathbf{q} + \epsilon_{\text{ProSelfLC}}\mathbf{p}, \\ \epsilon_{\text{ProSelfLC}} &= g(t) \times l(\mathbf{p}), \\ g(t) &= h(t/\Gamma - 0.5, B) \in (0, 1), \Rightarrow \text{Trusting learning time} \\ l(\mathbf{p}) &= 1 - H(\mathbf{p})/H(\mathbf{u}) \in (0, 1). \Rightarrow \text{Trusting sample confidence}\end{aligned}\tag{1}$$

$t$  and  $\Gamma$  are the iteration (time) counter and the number of total iterations, respectively.

$h(\cdot)$  is a logistic function where  $B$  controls its smoothness.

## To penalise or reward a low-entropy status?

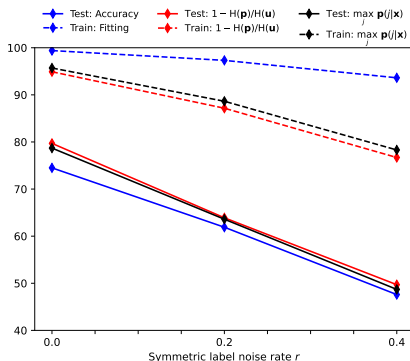

- OR methods penalise low entropy  $\Rightarrow$  OR is against entropy minimisation principle.
- LC rewards a low-entropy status  $\Rightarrow$  LC defends entropy minimisation principle.
  - LC has the same principle as the widely used expectation-maximization (EM) algorithm.

# CCE+ResNet18 on CIFAR-100

The final model is used for analysis when the training stops.

**Figure:** Our finding: as  $r$  increases, though the fitting of train set decreases little [13], the confidences of both sets drop significantly.

# Towards a low-temperature entropy state

Towards a curated low-entropy target state

- We apply a low temperature  $T$  to decrease the entropy of self knowledge. Other than using  $p$  to correct labels, we use

$$p_T(j|x) = \exp(z_j/T) / \sum_{m=1}^C \exp(z_m/T). \quad (2)$$

- An annealed temperature (denoted by  $AT$ ,  $0 < T < 1$ ) works best together with ProSelfLC.

# Protein classification

**Table:** Results of robust protein classification against cropping noise and symmetric label noise. For comprehensiveness, we report accuracy and confidence metrics on both train and test sets. We show two confidence metrics:  $1 - H(p)/H(u)$  and  $\max_j p(j|x)$ . We use the final model when training ends without selecting the intermediate best ones. The highest accuracy or confidence in each row is green-colored.

Noise type	Metric	Data	CCE	LS	CP	Boot-soft	ProSelfLC
Cropping noise	Accuracy	Test	88.7	90.4	90.9	90.4	92.4
		Train	99.3	99.3	98.8	95.9	91.8

# Summary

## ① ProSelfLC:

- enhances the similarity structure information over training classes.
- corrects the semantic classes of noisy label distributions.
- is the first method to trust self knowledge progressively and adaptively.
- learns towards a low-temperature entropy state.

## ② Our extensive experiments:

- defend the entropy minimisation principle.

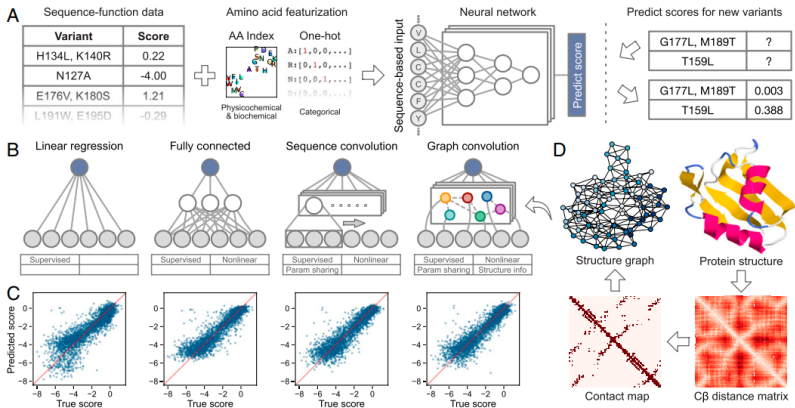

## ③ Code: <https://github.com/XinshaoAmosWang/ProSelfLC-AT>
